# Abstract

Útdráttur á ensku sem er að hámarki 250 orð.

# Útdráttur

Hér kemur útdráttur á íslensku sem er að hámarki 250 orð. Reynið að koma útdráttum á eina blaðsíðu en ef tvær blaðsíður eru nauðsynlegar á seinni blaðsíða útdráttar að hefjast á oddatölusíðu (hægri síðu).

# Preface

Formála má sleppa og skal þá fjarlægja þessa blaðsíðu. Formáli skal hefjast á odd-atölu blaðsíðu og nota skal Section Break (Odd Page).

Ekki birtist blaðsíðutal á þessum fyrstu síðum ritgerðarinnar en blaðsíðurnar teljast með og hafa áhrif á blaðsíðutal sem birtist með rómverskum tölum fyrst á efnisyfirliti.

# 1. Introduction

$\mathcal{O}(U)$  for open  $U \subset \mathbb{C}$  is the family of functions holomorphic on  $U$ .  $C(X)$  for open topological space  $X$  is the family of continuous functions from  $X$  to  $\mathbb{C}$ . We will use  $\mathbb{D}$  to refer to the open unit disk  $\{z \in \mathbb{C}; |z| < 1\}$ . The closed unit disk will get no special notation, but will be referred to by  $\overline{\mathbb{D}}$ . We will use  $\mathbb{T}$  to refer to the open unit circle  $\{z \in \mathbb{C}; |z| = 1\}$ .

## 2. Preliminaries

### 2.1. Measure theory

During introductory courses in measure theory the focus is often solely on positive measures [Tao, 2014], which are then simply referred to as ‘measures’. This restriction is immediately felt when studying functional analysis (see for example 2.3.7). We, therefore, need the following definitions:

**Definition 2.1.1.** Let  $\mathcal{F}$  be a  $\sigma$ -algebra and  $\mu : \mathcal{F} \rightarrow Y$ , where  $Y$  is a subset of  $\mathbb{C}$  or  $\overline{\mathbb{R}}$ . We say that  $\mu$  is *countably additive* if

$$\mu \left( \bigcup_{n \in \mathbb{N}} E_n \right) = \sum_{n \in \mathbb{N}} \mu(E_n)$$

for all disjoint collections  $(E_n)_{n \in \mathbb{N}}$  in  $\mathcal{F}$ . We also say that

- (i)  $\mu$  is a *positive measure* if it is countably additive and  $Y = [0, \infty]$ .
- (ii)  $\mu$  is a *real valued measure* if it is countably additive and  $Y = [-\infty, \infty[$  or  $Y = ]-\infty, \infty]$ .
- (iii)  $\mu$  is a *complex measure* if it is countably additive and  $Y = \mathbb{C}$ .

Allowing  $Y = \overline{\mathbb{R}}$  in (ii) would lead to trouble, for example if  $\mu(\{x\}) = \infty$  and  $\mu(\{y\}) = -\infty$  what is  $\mu(\{x, y\})$ ?

For those not familiar with complex measures, some care must be taken. A prime example is the notion of null sets. They still play a great role, but their definition is different. We can motivate this difference by letting  $X = \{x, y\}$ ,  $\mathcal{F}$  be the powerset of  $X$ , and define  $\mu$  by  $\mu(\{x\}) = -1$  and  $\mu(\{y\}) = 1$ . For  $\mu$  to be a measure we need  $\mu(X) = 0$  to hold. Blindly applying our definitions from positive measures would label  $X$  as a  $\mu$ -null set. This would of course technically be a valid definition, but leads to problems further down the road, for example

$$\int_X f \, d\mu = 0$$

## 2. Preliminaries

does not hold generally (once we define integration by complex measure, of course). To avoid this specific pitfall we define a measurable set  $E$  to be  $\mu$ -null if  $\mu(F) = 0$  holds for all measurable  $F$  such that  $F \subset E$ . The above example also shows us another pitfall,  $E \subset F \implies \mu(E) \leq \mu(F)$  doesn't hold generally.

If we have a complex measure  $\mu : \mathcal{F} \rightarrow \mathbb{C}$  we may want a positive measure  $\lambda$  that dominates it, in the sense that  $|\mu(E)| \leq \lambda(E)$ . We would also want  $\lambda$  to be 'small' in some sense. We will refer to a collection  $(E_n)_{n \in \mathbb{N}}$  in  $\mathcal{F}$  as a *partition of  $E$*  if they are pairwise disjoint and their union is  $E$ . The measure  $\lambda$  mentioned earlier will then satisfy

$$\lambda(E) = \sum_{n \in \mathbb{N}} \lambda(E_n) \geq |\mu(E)|.$$

It so happens that defining  $\lambda$  by

$$\lambda(E) = \sup \left\{ \sum_{n \in \mathbb{N}} |\mu(E_n)|; \text{ where } (E_n)_{n \in \mathbb{N}} \text{ is any partition of } E \right\}$$

yields a measure. This measure is referred to as *the total variation of  $\mu$*  and denoted by  $|\mu|$  (for example,  $|\mu|(E)$ ). A proof that  $|\mu|$  is a measure and more detail on complex measures can be found in chapter 6 of [Rudin, 1987].

## 2.2. Complex analysis in one variable

### 2.2.1. The disk algebra

**Definition 2.2.1.** A function is said to be in the *disk algebra* if it is holomorphic on  $\mathbb{D}$  and continuous on  $\overline{\mathbb{D}}$ . We will refer to this family of function  $\mathcal{A}$ .

It can be shown using Morera's theorem that a sequence of holomorphic function that converges uniformly has a holomorphic limit [Axelsson, 2014]. The same holds for continuous functions. So, naturally, we conclude that a sequence of functions in  $\mathcal{A}$  that converges uniformly has a limit in  $\mathcal{A}$ .

### 2.2.2. Carathéodory

**Definition 2.2.2.** A continuous function  $\gamma : [0, 1] \rightarrow \mathbb{C}$  is said to be a *Jordan curve* if  $\gamma(0) = \gamma(1)$  and

$$\gamma(s) = \gamma(t) \implies s = t \quad \text{for all } s, t \in ]0, 1[.$$

The definition above can be restated as: A Jordan curve is a closed simple curve. The term ‘simple’ here means that the curve is not self-intersecting. The name stems from a famous result by Camille Jordan stating that  $\mathbb{C} \setminus \gamma([0, 1])$  has two connected components, one of which is simply connected. The simply connected component will be called *the domain bounded by  $\gamma$* . The proof of this result is rather technical and outside the scope of this thesis [Greene and Krantz, 2006, Whyburn, 1958]. The result is however necessary to make statement such as ‘let  $U$  be the domain bounded by  $\gamma$ ’. An example of this is the following theorem:

**Theorem 2.2.3** (Carathéodory). *Let  $\Omega_1$  and  $\Omega_2$  be domains in  $\mathbb{C}$  each bounded by a Jordan curve and  $\Phi : \Omega_1 \rightarrow \Omega_2$  be a conformal mapping. There exists a continuous injection  $\hat{\Phi} : \overline{\Omega_1} \rightarrow \overline{\Omega_2}$  that extends  $\Phi$ .*

A proof of this can be found in section 13.2 of [Greene and Krantz, 2006].

### 2.2.3. The Riemann Mapping Theorem

We will start of with a definition.

**Definition 2.2.4.** A map  $f : U \rightarrow V$ , with open  $U, V \subset \mathbb{C}$  is said to be *conformal* if it is holomorphic, bijective, and its inverse is holomorphic.

The fact that the inverse is holomorphic is actually redundant. It can be shown that a holomorphic bijection has a holomorphic inverse. [Greene and Krantz, 2006]

**Theorem 2.2.5** (Riemann mapping theorem [Greene and Krantz, 2006]). *If  $U \subset \mathbb{C}$ ,  $U \neq \mathbb{C}$  is homeomorphic to  $\mathbb{D}$  then there exists a conformal mapping from  $\mathbb{D}$  to  $U$ .*

**Corollary 2.2.6.** *If  $U$  and  $V$  are both homeomorphic to  $\mathbb{D}$  then there exists a conformal mapping from  $U$  to  $V$ .*

*Proof.* The Riemann mapping theorem gives us  $\Phi_1$ , a conformal mapping from  $\mathbb{D}$  to  $U$ , and  $\Phi_2$ , a conformal mapping from  $\mathbb{D}$  to  $V$ . The desired conformal mapping from  $U$  to  $V$  is then  $\Phi_2 \circ \Phi_1^{-1}$ .  $\square$

In this thesis the disk algebra  $\mathcal{A}$  is of special interest so a version of the Riemann mapping theorem that considers continuity at the boundary is desirable. We can

## 2. Preliminaries

combine the Riemann mapping theorem and Carathéodory's theorem to achieve the desired theorem. The only thing to prove is that a homeomorphism  $f$  maps the boundary of a bounded set  $U$  to the boundary of  $f(U)$  and that a Jordan curve under a homeomorphism is still a Jordan curve.

**Corollary 2.2.7.** *If  $K$  is homeomorphic to  $\overline{\mathbb{D}}$  then there exists a continuous, injective  $\Phi : \overline{\mathbb{D}} \rightarrow K$  such that its restriction to  $\mathbb{D}$  is a conformal mapping.*

*Proof.* First, let  $U$  be a bounded, open set in  $\mathbb{C}$ ,  $f : \overline{U} \rightarrow \mathbb{C}$  be an injective continuous map, and let's show that  $\partial f(U) = f(\partial U)$ . Let  $p \in \partial U$  and  $B_r(z) = \{z \in \mathbb{C}; |r - z| < r\}$ . Let's also assume that  $f(p)$  is in the interior of  $f(U)$  and show that it leads to a contradiction. There exists an  $r > 0$  such that  $B_r(p) \subset f(U)$ , because the interior of a set is always open. This gives us as an open neighbourhood  $f^{-1}(B_r(p)) \subset U$  of  $p$ , but  $p \in \partial U$  implies that no such neighbourhood exists. So  $f(p) \in \partial f(U)$ , implying  $\partial f(U) \supset f(\partial U)$ . We can use the same argument to show that  $\partial f(U) \subset f(\partial U)$ , since  $f$  is bijective if we consider it as a map from  $\overline{U}$  into  $f(\overline{U})$ . So  $f(\partial U) = \partial f(U)$ .

Second, let  $U$  and  $V$  be open sets in  $\mathbb{C}$ ,  $\gamma : [0, 1] \rightarrow \partial \mathbb{D}$  a Jordan curve,  $f : U \rightarrow V$  be homeomorphism, Let  $\lambda = f \circ \gamma$  and  $s, t \in ]0, 1[$  such that  $\lambda(s) = \lambda(t)$ . It suffices to show that  $s = t$ , since  $\lambda(0) = \lambda(1)$  obviously holds. We have that  $f(z) = f(w)$  implies  $z = w$ , since  $f$  is bijective, and therefore injective. So  $\lambda(s) = (f \circ \gamma)(s) = (f \circ \gamma)(t) = \lambda(t)$  implies that  $\gamma(s) = \gamma(t)$ . But  $\gamma$  is a Jordan curve, so  $\gamma(s) = \gamma(t)$  implies  $s = t$ . So  $\lambda$  is also a Jordan curve.

Finally, we can prove the corollary. Let  $f$  be a homeomorphism from  $\overline{\mathbb{D}}$  to  $K$ . The Riemann mapping theorem also gives us a conformal map  $\Phi : \mathbb{D} \rightarrow f(\mathbb{D})$ . We know that  $\overline{\mathbb{D}}$  is compact, so  $K = f(\overline{\mathbb{D}})$  is also compact, since the image of a compact set under a continuous mapping is also compact. Moreover,  $K$  is bounded. So  $f(\partial \mathbb{D}) = \partial f(\mathbb{D}) = \partial K$  according to our first step and  $\partial K$  is a Jordan curve according to the second step, since  $\partial \mathbb{D}$  is a Jordan curve. So  $\Phi$  is a conformal map between two domains, each bounded by a Jordan curve. This allows us to use Carathéodory's theorem to extend  $\Phi$  continuously and injectively to  $\overline{\mathbb{D}}$ , concluding the proof.  $\square$

The Riemann mapping theorem is a strong tool when analyzing holomorphic functions on simply connected domains. We can often solve things for the unit disk (or unit square as in 3.2.2) and then map that solution to a general simply connected domain.

We will briefly touch on multivariate complex analysis so we will need a definition of a holomorphic function in  $\mathbb{C}^n$ . If  $U \subset \mathbb{C}^n$  is open and  $f : U \rightarrow \mathbb{C}$  such that  $f$  is holomorphic in each variable separately we say that  $f$  is *holomorphic on  $U$* .

## 2.3. Functional analysis

**Definition 2.3.1.** Let  $X$  be a topological space. We say that  $X$  is *locally compact* if for each  $x \in X$  there exists a open set  $U_x$  such that  $x \in U_x$  and  $\overline{U_x}$  is compact.

**Definition 2.3.2.** Let  $X$  be a locally compact space. We say a complex function  $f$  *vanishes at infinity* if for all  $\varepsilon > 0$  there exists a compact set  $K$  such that  $|f(x)| < \varepsilon$  for all  $x \in X \setminus K$ . The family of all such functions is referred as  $C_0(X)$ .

Let  $X$  be compact. Then if  $f \in C(X)$  and  $\varepsilon > 0$  we set  $K = X$  and see that  $|f(x)| < \varepsilon$  vacuously holds for all  $x \in X \setminus K = \emptyset$ . So  $C(X)$  and  $C_0(X)$  are identical in this case.

**Definition 2.3.3.** Let  $\alpha$  be a linear map from a normed vector space  $X$  into a normed vector space  $Y$ . We define a its *norm* by

$$\|\alpha\| = \sup\{\|\alpha(x)\|; \|x\| < 1\}$$

and say  $\alpha$  is *bounded* if its norm is finite.

**Theorem 2.3.4.** If  $\alpha$  is a linear map from a normed vector space  $X$  into a normed vector space  $Y$  then the following properties are equivalent:

- (i)  $\alpha$  is bounded.
- (ii)  $\alpha$  is continuous.
- (iii)  $\alpha$  is continuous at  $x \in X$ .

This theorem allows us to use the terms ‘bounded’ and ‘continuous’ interchangeably when talking about linear mappings between normed vector spaces. A proof of this theorem can be found on page 96 in [Rudin, 1987].

Let’s recall what the  $L^p$  spaces are. Let  $X$  be a space with  $\sigma$ -algebra  $\mathcal{F}$ , and  $\mu$  be a measure on that  $\sigma$ -algebra. We say a function is in  $\mathcal{L}^1(X, \mu)$  if

$$\int |f| d\mu < \infty$$

and we say it is  $\mathcal{L}^p(X, \mu)$  if  $|f|^p$  is in  $\mathcal{L}^1$ , for  $0 < p < \infty$ . We then define an equivalence relation  $\sim$  such that  $f \sim g$  if and only if  $\mu(\{x \in X; f(x) \neq g(x)\}) = 0$ .

## 2. Preliminaries

We define  $L^p(X, \mu)$  to be the quotient space  $\mathcal{L}(X, \mu)/\sim$ . The space  $L^p(X, \mu)$  has one major benefit over  $\mathcal{L}^p(X, \mu)$ ,

$$\|f\|_p = \left( \int |f|^p d\mu \right)^{1/p}$$

is a norm on  $L^p(X, \mu)$ . We sometimes write  $L^p(\mu)$  if the space in question is obvious from context and  $L^p(X)$  if the measure is obvious from context.

### 2.3.1. Hahn-Banach

There are many related theorems going by the name ‘Hahn-Banach Theorem’. These are sometimes split in two groups, ‘separation theorems’ and ‘extension theorems’. When proving 3.3.1 we need the following Hahn-Banach separation theorem:

**Theorem 2.3.5** ([Pryce, 1973]). *Let  $X$  be a locally convex normed vector space,  $A \neq \emptyset$  be a closed convex subset of  $X$ , and  $p \in X \setminus A$ . Then there exists a continuous linear functional  $f$  such that  $\sup\{f(x); x \in A\} < 1$  and  $f(p) > 1$ .*

### 2.3.2. The Riesz representation theorem

Let  $X$  be a space with  $\sigma$ -algebra and measure  $\mu$ , choose  $p$  and  $q$  such that  $1 < p, q < \infty$  and  $1/p + 1/q = 1$ , and  $g \in L^q(\mu)$ . We can then define a linear transform

$$\alpha(f) = \int fg d\mu.$$

The Hölder inequality tells us it is bounded.

**Theorem 2.3.6** (The Riesz representation theorem for bounded linear functionals on  $L(X, \mu)$  with  $\sigma$ -finite  $X$  [Rudin, 1987]). *Let  $1 < p < \infty$ ,  $q$  be such that  $1/p + 1/q = 1$ ,  $\mu$  be a  $\sigma$ -finite positive measure on  $X$ , and  $\alpha$  be a bounded linear functional on  $L^p(\mu)$ . There then exists a unique  $g \in L^q(\mu)$  such that*

$$\alpha(f) = \int fg d\mu$$

for all  $f \in L^p(\mu)$  and

$$\|\alpha\| = \|g\|_q.$$

Note that the theorem above also hold for  $p = 1$  and  $q = \infty$ , but we will not need that result.

**Theorem 2.3.7** (The Riesz representation theorem for bounded linear functionals on  $C_0(X)$  with locally compact  $X$  [Rudin, 1987]). *Let  $X$  be a locally compact Hausdorff space and  $\alpha$  be a bounded linear functional on  $C_0(X)$ . There then exists a measure  $\mu$  such that*

(i)

$$\alpha(f) = \int_X f \, d\mu$$

for all  $f \in C_0(X)$  and

(ii)

$$\|\alpha\| = |\mu|(X).$$

## 3. Rudin-Carleson theorem

### 3.1. F. and M. Riesz theorem

The main result of this section is that the annihilating measures of

$$\mathcal{A}|_{\mathbb{T}} = \{f|_{\mathbb{T}}; f \in \mathcal{A}\}$$

are absolutely continuous with respect to the Lebesgue measure. We will show this to be a corollary of the F. and M. Riesz theorem, which we will prove in the manner of [Rudin, 1987]. To attain the main result of this section we need some lemmas and definitions. To prove one of the lemmas we will also use the following two famous theorems:

**Definition 3.1.1.** Let  $\mathcal{F}$  be a family of complex functions on a metric space  $(X, d)$ .

We say that the family is *pointwise bounded* if for all  $x \in X$  there exists a constant  $M < \infty$  such that

$$|f(x)| < M, \text{ for all } f \in \mathcal{F}.$$

Note that  $M$  may depend on  $x$ .

We say that the family is *equicontinuous* if for all  $\varepsilon > 0$  there exists a  $\delta > 0$  such that

$$|f(x) - f(y)| < \varepsilon, \text{ for all } f \in \mathcal{F} \text{ and } x, y \in X \text{ such that } d(x, y) < \delta.$$

Note here that  $\delta$  is globally defined and only dependent on  $\varepsilon$ .

**Theorem 3.1.2** (Bolzano-Weierstrass). *Let  $(a_n)_{n \in \mathbb{N}}$  be a sequence of numbers in  $\mathbb{R}^n$ , such that  $|a_n| < M < \infty$ , for all  $k \in \mathbb{N}$ . There than exists and infinite  $S \subset \mathbb{N}$  such that  $(a_n)_{n \in S}$  is convergent.*

*Proof.* Let's first assume that the sequence is in  $\mathbb{R}$ , that no element in it is repeated infinitely often (there is nothing to prove in that case), and that  $a_n \in ]0, 1[$  for all

### 3. Rudin-Carleson theorem

$n \in \mathbb{N}$ . The last assumption can be done with out loss of generality by studying the sequence  $((a_n + M)/(2M))_{n \in \mathbb{N}}$  instead. We will obtain the subsequence by a diagonal process. Let  $S_0 = \mathbb{N}$ ,  $S_0^- = \{n \in S_0; a_n < 1/2\}$ , and  $S_0^+ = \{n \in S_0; a_n > 1/2\}$ . We then set  $S_1 = S_0^-$  if it is infinite, but  $S_1 = S_0^+$  otherwise. This gives us a subsequence  $(a_n)_{n \in S_1}$  such that

$$\sup_{n \in S_1} a_n - \inf_{n \in S_1} a_n < 1/2.$$

We can then repeat this to get a sequence of sets  $(S_n)_{n \in \mathbb{N}}$  such that  $S_0 \supset S_1 \supset S_2 \supset \dots$  and

$$\sup_{n \in S_k} a_n - \inf_{n \in S_k} a_n < 2^{1-k},$$

for all  $k \in \mathbb{N}$ . Specifically, if we have  $S_k$  we set

$$U = m2^{-k}, \quad L = (m+1)2^{-k}$$

$S_k^- = \{n \in S_k; a_n < (U+L)/2\}$ , and  $S_k^+ = \{n \in S_k; a_n > (U+L)/2\}$ . We now set  $S_{k+1} = S_k^-$  if it has infinitely many elements, otherwise we set  $S_{k+1} = S_k^+$ . We conclude our construction by setting

$$S = \bigcup_{n \in \mathbb{N}} r_n,$$

where  $r_n$  is the  $n$ -th smallest element of  $S_n$ . This gives us the convergent sequence  $(a_n)_{n \in S}$  with limit

$$\sum_{k=0}^{\infty} \delta_k 2^{-k}$$

where

$$\delta_k = \begin{cases} 0, & \text{if we chose } S_k^- \\ 1, & \text{if we chose } S_k^+ \end{cases}.$$

To show the result for  $\mathbb{R}^n$  we can start by finding a subsequence such that the first coordinate is convergent. We can then choose a subsequence thereof such that the second coordinate is also convergent. Now the first two coordinates are convergent. If we do this  $n-2$  more times we get a desired subsequence.  $\square$

**Remark 3.1.3.** The theorem above clearly holds for sequences in  $\mathbb{C}$  as well.

**Theorem 3.1.4** (Ascoli-Arzelà). *Let  $\mathcal{F}$  be a pointwise bounded equicontinuous collection of complex functions on a metric space  $(X, d)$ , and  $X$  contains a countable dense subset. Then every sequence in  $\mathcal{F}$  contains a subsequence that converges uniformly on every compact subsets of  $X$ .*

*Proof.* Let  $E$  be a countable dense subset of  $X$ ,  $(f_n)_{n \in \mathbb{N}}$  be a series in  $\mathcal{F}$ , and  $x_1, x_2, \dots$  be an enumeration of  $E$ . We will prove the theorem in two steps. The first step is finding a subsequence of  $(f_n)_{n \in \mathbb{N}}$  that's pointwise convergent on  $E$  using the pointwise boundedness along with Bolzano-Weierstrass. The second step is using the equicontinuity to show that this gives us uniform continuity on compact subsets.

Let's first set  $S_0 = \mathbb{N}$ . Pointwise boundedness gives us that the sequence  $(f_n(x_1))_{n \in S_0}$  has a convergent subsequence. Let  $S_1$  index that subsequence. We can use this process to generate sets  $S_0 \supset S_1 \supset \dots$  such that  $(f_n(x_k))_{n \in S_k}$  is convergent. We then set

$$S = \bigcup_{k \in \mathbb{N}} r_k$$

where  $r_n$  is the  $k$ -th smallest element of  $S_k$ . We now have concluded the first step of the proof.

We will now assume the  $(f_n)_{n \in \mathbb{N}}$  is pointwise convergent on  $E$ , let  $K$  be a compact subset of  $X$ , and  $\varepsilon > 0$ . Equicontinuity gives us a  $\delta > 0$  such that  $d(x, y) < \delta$  implies that  $|f_n(x) - f_n(y)| < \varepsilon/3$ , for all  $n$ . Let's now cover  $K$  with  $m$  balls of radius  $\delta/2$  and call the  $k$ -th ball  $B_k$ . We can now set  $p_k$  as a point in  $B_k \cap E$ . This point exists because  $E$  is dense in  $X$ . Pointwise convergence on  $E$  let's us chose an  $N$  such that  $|f_{n_1}(p_k) - f_{n_2}(p_k)| < \varepsilon/3$  for  $k = 1, 2, \dots, m$  and all  $n_1, n_2 > N$ . Let's conclude by setting  $x \in K$ . Then there is a  $k$  such that  $x \in B_k$  and thus  $d(x, p_k) < \delta$ . The choice of  $\delta$  and  $N$  then gives us that

$$\begin{aligned} |f_{n_1}(x) - f_{n_2}(x)| &\leq |f_{n_1}(x) - f_{n_1}(p_k)| + |f_{n_1}(p_k) - f_{n_2}(p_k)| + |f_{n_2}(p_k) - f_{n_2}(x)| \\ &< \varepsilon/3 + \varepsilon/3 + \varepsilon/3 \\ &= \varepsilon. \end{aligned}$$

□

**Definition 3.1.5.** The function

$$P_r(t) = \sum_{n \in \mathbb{Z}} r^{|n|} e^{int}$$

for  $0 \leq r < 1$ ,  $t \in \mathbb{R}$ , is referred to as *the Poisson kernel on  $\mathbb{D}$* , or sometimes simply *the Poisson kernel*. We also rewrite  $P_r(\theta - t)$  by setting  $z = re^{it}$  as

$$P(z, e^{it}) = \frac{1 - |z|^2}{|e^{it} - z|^2}.$$

This stems from the fact that

$$P_r(\theta - t) = \operatorname{Re} \left( \frac{e^{it} + z}{e^{it} - z} \right) = \frac{1 - r^2}{1 - 2r \cos(\theta - r) + r^2}.$$

### 3. Rudin-Carleson theorem

For  $f \in L^1(\mathbb{T})$  we define the *Poisson integral* of  $f$  by

$$P[f](z) = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(e^{it}) P(z, e^{it}) dt.$$

For complex measure  $\mu$  we define the *Poisson integral* of  $\mu$  by

$$P[d\mu](z) = \int_{\mathbb{T}} P(z, e^{it}) d\mu(e^{it}).$$

Let's take a look at some of the properties of the Poisson kernel and Poisson integral. Note that both  $P[f]$  and  $P[d\mu]$  are defined on  $\mathbb{D}$  because of the way we defined the Poisson kernel.

We see that, since

$$P_r(t) = \frac{1 - r^2}{1 - 2r \cos(t) + r^2},$$

both  $P_r(t) > 0$  and  $P_r(t) = P_r(-t)$ . It will also come of use to know that for  $n \neq 0$

$$\int_{-\pi}^{\pi} e^{int} dt = (e^{in\pi} - e^{-in\pi}) = (e^{in\pi} - e^{-i(2n\pi - n\pi)}) = (e^{in\pi} - e^{in\pi}) = 0,$$

so

$$\begin{aligned} \int_{-\pi}^{\pi} P_r(t) dt &= \int_{-\pi}^{\pi} \sum_{n \in \mathbb{Z}} r^{|n|} e^{int} dt \\ &= \sum_{n \in \mathbb{Z}} \int_{-\pi}^{\pi} r^{|n|} e^{int} dt \\ &= \int_{-\pi}^{\pi} dt \\ &= 2\pi. \end{aligned}$$

This naturally leads us to the following lemma:

**Lemma 3.1.6.** Let  $\mu$  be a complex Borel measure, and  $u = P[d\mu]$ . Then

$$\|u_r\|_1 \leq \|\mu\|.$$

*Proof.* We have that

$$\begin{aligned}
 \|u\|_1 &= \frac{1}{2\pi} \int_{-\pi}^{\pi} |u(re^{i\theta})| d\theta \\
 &= \frac{1}{2\pi} \int_{-\pi}^{\pi} \left| \int_{\mathbb{T}} P(re^{i\theta}, e^{it}) d\mu(e^{it}) \right| d\theta \\
 &\leq \frac{1}{2\pi} \int_{-\pi}^{\pi} \int_{\mathbb{T}} P(re^{i\theta}, e^{it}) d|\mu(e^{it})| d\theta \\
 &= \int_{\mathbb{T}} \frac{1}{2\pi} \int_{-\pi}^{\pi} P(re^{i\theta}, e^{it}) d\theta d|\mu(e^{it})| \\
 &= \int_{\mathbb{T}} d|\mu(e^{it})| \\
 &= |\mu|(\mathbb{T}) \\
 &= \|\mu\|.
 \end{aligned}$$

□

The main reason we are developing these tools is to prove the F. and M. Riesz theorem. The theorem gives us a sufficient condition for when a measure  $\mu$  (on  $\mathbb{T}$ ) is absolutely continuous with regards to the Lebesgue-measure (on  $\mathbb{T}$ ). The proof is rather simple, we let  $f$  be the Poisson integral of  $\mu$  and  $h$  be a function such that its Poisson integral is  $f$ . We then show that  $d\mu = h dm$ . The following lemmas show that all this is in fact possible.

**Lemma 3.1.7.** Let  $u$  be harmonic in  $\mathbb{D}$  and

$$\sup_{0 < r < 1} \|u_r\|_1 = M < \infty.$$

Then there exists a unique complex Borel measure  $\mu$  on  $\mathbb{T}$  such that  $u = P[d\mu]$ .

**Lemma 3.1.8.** Let  $u$  be harmonic in  $\mathbb{D}$  and

$$\sup_{0 < r < 1} \|u_r\|_2 = M < \infty.$$

Then there exists a unique function  $f$  in  $L^2(\mathbb{T})$  such that  $u = P[f]$ .

We will need the following lemma in the proofs of 3.1.7 and 3.1.8:

**Lemma 3.1.9.** Let  $X$  be a separable Banach space,  $(\Gamma_n)_{n \in \mathbb{N}}$  be a sequence of linear functionals on  $X$ , and  $\sup_n \|\Gamma_n\| = M < \infty$ . Then there exists a subsequence  $(\Gamma_{n_i})_{i \in \mathbb{N}}$  such that the limit

$$\Gamma x = \lim_{k \rightarrow \infty} \Gamma_{n_k} x$$

exists for every  $x \in X$ . Furthermore,  $\Gamma$  is linear and  $\|\Gamma\| \leq M$ .

### 3. Rudin-Carleson theorem

*Proof.* We have that  $|\Gamma_n x| \leq M\|x\|$  and

$$\begin{aligned} |\Gamma_n x - \Gamma_n y| &= |\Gamma_n(x - y)| \\ &\leq M\|x - y\|. \end{aligned}$$

The first inequality gives us pointwise boundedness and the second gives us equicontinuity. Now, since singletons are compact, Ascoli-Arzelà gives us a subsequence, let's index it by  $S$ , such that  $(\Gamma_n x)_{n \in S}$  is convergent for all  $x \in X$ . Let's now define  $\Gamma$  by

$$\Gamma(x) = \lim_{k \in S} \Gamma_k x,$$

see the

$$\begin{aligned} \Gamma(x) + \Gamma(y) &= \lim_{k \in S} \Gamma_k x + \lim_{k \in S} \Gamma_k y \\ &= \lim_{k \in S} (\Gamma_k x + \Gamma_k y) \\ &= \lim_{k \in S} \Gamma_k(x + y) \\ &= \Gamma(x + y), \end{aligned}$$

where the second equality holds because addition is continuous, and  $a\Gamma(x) = \Gamma(ax)$  obviously holds. So  $\Gamma$  is linear. Lastly

$$\begin{aligned} \|\Gamma\| &= \sup\{|\Gamma x|; \|x\| \leq 1\} \\ &= \sup\left\{\left|\lim_{n \in S} \Gamma_n x\right|; \|x\| \leq 1\right\} \\ &\leq \sup\{M; \|x\| \leq 1\} \\ &= M. \end{aligned}$$

□

*Proof of 3.1.7.* Let  $\Gamma_r$ , for  $r \in [0, 1[$ , be linear functionals on  $C(\mathbb{T})$  defined by

$$\Gamma_r g = \int_{\mathbb{T}} g u_r d\sigma.$$

If  $\|g\| \leq 1$  is assumed we get that

$$\Gamma_r g = \int_{\mathbb{T}} g u_r d\sigma \leq \int_{\mathbb{T}} u_r d\sigma = \|u_r\|_1 \leq M.$$

so

$$\|\Gamma_r\| \leq M.$$

By Lemma 3.1.9 and the Riesz representation theorem we get a measure  $\mu$  on  $\mathbb{T}$  with  $\|\mu\| \leq M$ , and a sequence  $(r_n)_{n \in \mathbb{N}}$  on  $[0, 1[$  with limit 1, such that

$$\lim_{n \rightarrow \infty} \int_{\mathbb{T}} g u_{r_n} d\sigma = \int_{\mathbb{T}} g d\mu \quad (3.1)$$

for all  $g \in C(\mathbb{T})$ . Let's now define functions  $h_k$  on  $\overline{\mathbb{D}}$  by  $h_k(z) = u(r_k z)$ . We get that, since  $u$  is harmonic on  $r\mathbb{D}$  for  $r \in ]0, 1[$ , the functions  $h_k$  are harmonic on  $\mathbb{D}$  and continuous on  $\overline{\mathbb{D}}$ . So each of them can be represented by the Poisson integral of their restriction to  $\mathbb{T}$ . Note that  $h_k(e^{it}) = u_{r_k}(e^{it})$ , so

$$\begin{aligned} u(z) &= \lim_{n \rightarrow \infty} u(r_n z) \\ &= \lim_{n \rightarrow \infty} h_n(z) \\ &= \lim_{n \rightarrow \infty} \int_{\mathbb{T}} P(z, e^{it}) h_n(e^{it}) d\sigma(e^{it}) \\ &= \lim_{n \rightarrow \infty} \int_{\mathbb{T}} P(z, e^{it}) u_{r_n}(e^{it}) d\sigma(e^{it}) \\ &= \int_{\mathbb{T}} P(z, e^{it}) d\mu(e^{it}) \\ &= P[d\mu](z), \end{aligned}$$

where the fifth equality is achieved by putting  $g = P(z, e^{it})$  into 3.1. This concludes the proof of existence.

Let's assume that  $P[d\mu] = 0$ , and let  $f \in C(\mathbb{T})$ ,  $u = P[f]$  and  $v = P[d\mu]$ . We firstly have the symmetry

$$P(re^{i\theta}, e^{it}) = P(re^{it}, e^{i\theta}).$$

This symmetry is due to

$$|e^{it} - re^{i\theta}| = |1 - re^{i(\theta-t)}| = |1 - re^{i(t-\theta)}| = |e^{i\theta} - re^{it}|,$$

which is geometrically intuitive. The first and last equalities hold because the distance between two points doesn't change under rotation and the second equality holds because the distance from  $z$  to a real number  $a$  is the same distance from  $\bar{z}$  to  $a$ . We now obtain

$$\begin{aligned} \int_{\mathbb{T}} u_r d\mu &= \int_{\mathbb{T}} \int_{-\pi}^{\pi} P(re^{i\theta}, e^{it}) f(e^{i\theta}) d\theta d\mu(e^{it}) \\ &= \int_{-\pi}^{\pi} f(e^{i\theta}) \int_{\mathbb{T}} P(re^{it}, e^{i\theta}) d\mu(e^{it}) d\theta \\ &= \int_{-\pi}^{\pi} f(e^{i\theta}) v_r d\theta \\ &= \int_{\mathbb{T}} f v_r d\sigma. \end{aligned}$$

If we let  $r \rightarrow 1$  we get

$$\int_{\mathbb{T}} f d\mu = 0.$$

This holds for all  $f \in C(\mathbb{T})$ , so the measure  $\mu$  represents zero in the dual of  $C(\mathbb{T})$ . The Riesz representation theorem then tells us that  $|\mu|(\mathbb{T}) = 0$ , so  $\mu = 0$ .

### 3. Rudin-Carleson theorem

Now let  $\lambda$  and  $\nu$  be measures on  $\mathbb{T}$  such that  $P[d\lambda] = P[d\nu]$ . We have that  $P[d(\lambda - \nu)] = 0$ , so, as shown above  $\lambda - \nu = 0$ . Moreover  $\lambda = \nu$ , which concludes the proof of uniqueness.  $\square$

*Proof of 3.1.8.* The proof of existence is almost identical to that proof of existence in 3.1.7 and the uniqueness is shown in the same manner. The differences in the existence proofs are in the beginning when we are choosing what function spaces we use and which theorems to references. Now we define  $\Gamma_r$  in the same way, except we define it on  $L^2(\mathbb{T})$ . We again use 3.1.9 and the (other) Riesz representation theorem to show that there exists a function  $f$  in  $L^2(\mathbb{T})$  with  $\|f\|_2 \leq M$  and

$$\lim_{n \rightarrow \infty} \int_{\mathbb{T}} g u_{r_n} d\sigma = \int_{\mathbb{T}} g f d\sigma$$

for all  $g$  in  $L^2(\mathbb{T})$ . The remaining calculations are unchanged.  $\square$

We see by this proof that 3.1.8 could be generalized trivially to find a function  $f$  in  $L^p(\mathbb{T})$  such that  $P[f] = u$  for harmonic  $u$  with

$$\sup_{0 < r < 1} \|u_r\|_p = M < \infty$$

and  $p > 1$ . We can't use this method for  $p = 1$  since we will need to use the Riesz representation theorem for the exponent conjugate of  $p$ , and the theorem only holds if it is in  $[1, \infty[$ .

We have not yet shown any condition for a function  $f$  that implies there exists a  $h \in L^1(\mathbb{T})$  such that  $P[h] = f$ . For that we need the following definitions:

**Definition 3.1.10.** For a function  $f$  holomorphic on  $\mathbb{D}$  we define

$$\|f\|_{H^p} = \sup_{0 < r < 1} \left( \frac{1}{2\pi} \int_{-\pi}^{\pi} |f(re^{i\theta})|^p d\theta \right)^{1/p}$$

and we say that  $f$  is in  $H^p$  if  $\|f\|_{H^p} < \infty$ . These spaces are referred to as the *Hardy spaces*.

A useful result from the theory of Hardy spaces is if  $f \in H^1$  then there exist  $g, h \in H^2$  such that  $f = g \cdot h$  and  $|f| < |g|$  [Rudin, 1987, Theorem 17.10].

**Definition 3.1.11.** Let  $0 < \alpha < 1$ . We refer to the open convex hull of

$$\{z \in \mathbb{C}; |z| < \alpha\} \cup \{1\},$$

Figure 3.1: A visualization of  $\Omega_\alpha$ , for a moderately large  $\alpha$ . Note that the only boundary point included in  $\Omega_\alpha$  is 1.

that also includes 1, as *the nontangential approach region of 1*, denoted by  $\Omega_\alpha$ . We will also use the rotated version,  $e^{i\theta}\Omega_\alpha$ . Let  $u : \mathbb{D} \rightarrow \mathbb{C}$ . Its *nontangential maximal function* is defined on  $\mathbb{T}$  by

$$(N_\alpha u)(e^{it}) = \sup\{|u(z)|; z \in e^{it}\Omega_\alpha\}.$$

We say that  $u$  has *nontangential limit*  $\lambda$  at  $e^{it}$  if, for all  $0 < \alpha < 1$ ,

$$\lim_{k \rightarrow \infty} u(z_k) = \lambda$$

for all sequences  $(z_k)_{k \in \mathbb{N}}$  in  $e^{it}\Omega_\alpha$  that converge to  $e^{it}$ .

**Lemma 3.1.12.** If  $f$  is in  $H^1$  then

1. its nontangential limits,  $F$ , exist almost everywhere on  $\mathbb{T}$ ,
2.  $F$  is in  $L^1(\mathbb{T})$ , and
3.  $f = P[F]$ .

*Proof.* Let  $g$  and  $h$  be functions in  $L^2(\mathbb{T})$  such that  $f = g \cdot h$ , as described above. We have by Lemma 3.1.8 functions  $G$  and  $H$  in  $L^2(\mathbb{T})$  such that  $g = P[G]$  and  $h = P[H]$ . Theorem 11.23 in [Rudin, 1987] (along with discussion on the prior page) states that if  $h$  is in  $L^1(\mathbb{T})$  then  $P[h]$  has nontangential limit  $h(e^{it})$  at almost

### 3. Rudin-Carleson theorem

every  $e^{it}$ . We also have by the Hölder inequality that on a finite measure space (such as  $\mathbb{T}$  with the Lebesgue measure)  $\|h\|_1 \leq \|h\|_2$ . So  $g$  and  $h$  have nontangential limits almost everywhere on  $\mathbb{T}$ . This tells us that  $f$  also has nontangential limits almost everywhere on  $\mathbb{T}$ , since  $f = g \cdot h$ . By  $f \leq h^2$  we have that  $N_\alpha f \leq (N_\alpha h)^2$ , and therefore  $N_\alpha f \in L^1(\mathbb{T})$ . Let  $F$  be the tangential limit of  $f$ . We have that  $|F| \leq N_\alpha f$  where  $F$  is defined, so  $F$  is also in  $L^1(\mathbb{T})$ . Note that

$$\lim_{r \rightarrow 1} \|F - f_r\|_1 = \lim_{r \rightarrow 1} \int |F - f_r| d\sigma = 0$$

since  $f_r \rightarrow F$  holds almost everywhere and  $|f_r| < N_\alpha f$  let's us use dominated convergence. We can also represent  $f_r$  by its Poisson integral, for  $r < 1$ , that is

$$f_r(z) = \frac{1}{2\pi} \int_{-\pi}^{\pi} P(z, e^{it}) f_r(e^{it}) dt.$$

Letting  $r$  go to 1 gives us

$$f(z) = \frac{1}{2\pi} \int_{-\pi}^{\pi} P(z, e^{it}) F(e^{it}) dt,$$

namely,  $f$  is the Poisson integral of  $F$ . □

**Theorem 3.1.13** (F. and M. Riesz theorem). *If  $\mu$  is a complex Borel measure on  $\mathbb{T}$  and*

$$\int e^{-int} d\mu = 0$$

*for  $n = -1, -2, \dots$ , then  $\mu \ll m$ .*

If we take a second look at the outline of proof given earlier we see that most of the work has been done. All that's left is to show that the condition given in the theorem implies that  $P[d\mu]$  is in  $H^1$ .

*Proof.* Let  $f = P[d\mu]$ . If we set  $z = re^{i\theta}$  we get that

$$P(z, e^{it}) = P_r(\theta - t) = \sum_{n \in \mathbb{Z}} r^{|n|} e^{in(\theta-t)} = \sum_{n \in \mathbb{Z}} r^{|n|} e^{in\theta} e^{-int}.$$

We can use the assumption of the theorem to write  $f$  as a power series by

$$\begin{aligned}
 f(z) &= \int_{\mathbb{T}} P(z, e^{it}) d\mu(e^{it}) \\
 &= \int_{\mathbb{T}} \sum_{n \in \mathbb{Z}} r^{|n|} e^{in\theta} e^{-int} d\mu(e^{it}) \\
 &= \sum_{n \in \mathbb{Z}} r^{|n|} e^{in\theta} \int_{\mathbb{T}} e^{-int} d\mu(e^{it}) \\
 &= \sum_{n=0}^{\infty} r^n e^{in\theta} \int_{\mathbb{T}} e^{-int} d\mu(e^{it}) \\
 &= \sum_{n=0}^{\infty} \hat{\mu}_n z^n,
 \end{aligned}$$

where  $\hat{\mu}_n$  is the  $n$ -th Fourier coefficient of  $\mu$ . This along with 3.1.6 gives us that  $f \in H^1$ . We can now define a  $h \in L^1(\mathbb{T})$ , by 3.1.12, such that  $f = P[h]$ . It follows from 3.1.7 that  $d\mu = h d\sigma$ . □

**Corollary 3.1.14.** *Every annihilating measures of  $\mathcal{A}|_{\mathbb{T}}$  is absolutely continuous with regards to the Lebesgue-measure on  $\mathbb{T}$ .*

*Proof.* Let  $\mu$  be an annihilating measure of  $\mathcal{A}|_{\mathbb{T}}$ . By definition we have that

$$\int f d\mu = 0$$

for all  $f \in \mathcal{A}|_{\mathbb{T}}$ . Now since  $t \mapsto e^{-int}$  is entire for  $n = -1, -2, \dots$  we have that their restriction to  $\mathbb{T}$  are in  $\mathcal{A}|_{\mathbb{T}}$ . Thus,

$$\int e^{-int} d\mu = 0$$

for all  $n = -1, -2, \dots$  and  $\mu \ll m$ . □

## 3.2. Rudin-Carleson theorem

We will refer to the *closed unit square* in  $\mathbb{C}$  by

$$S = \{z; |\max(\operatorname{Re} z, \operatorname{Im} z)| \leq 1\}.$$

The square with side-lengths  $a$  and bottom-left corner at  $w$  is then denoted by  $w + aS$ .

### 3. Rudin-Carleson theorem

To adequately discuss the main result of this theorem we need a few fundamentals about closed set in  $\mathbb{R}$  of Lebesgue-measure zero. Let  $K$  be such a set. We can show by contradiction that  $K$  is totally disconnected. Recall that a set is totally disconnected if each connected component is a singleton. If  $K$  was not totally disconnected it would have an open subset meaning its measure could not be zero. Another important thing to note is that  $K$  could include an uncountable number of elements. Results like 3.2.3 would be trivial if this were not the case. A famous example of an uncountable, closed set of Lebesgue-measure zero is the Cantor set. We will also make use of the following lemma:

**Lemma 3.2.1.** Let  $\varepsilon > 0$ ,  $K$  be a closed subset of  $\mathbb{T}$  of Lebesgue-measure zero, and  $f : K \rightarrow \mathbb{C}$ . Then there exist pairwise disjoint  $E_1, E_2, \dots, E_n$  and  $w_1, w_2, \dots, w_n$  such that

$$E_1 \cup E_2 \cup \dots \cup E_n = K$$

and

$$f(E_k) \subset w_k + \varepsilon S \quad k = 1, 2, \dots, n.$$

*Proof.* We know that  $f(K)$  is compact, so we can choose  $w$  and  $a$  such that  $f(K) \subset w + aS$ . □

In the discussion before the proof of 3.2.3 a logarithm is used. This is the base 2 logarithm, specifically it satisfies  $\log 2^x = x$ .

**Theorem 3.2.2** (Rudin-Carleson theroem). *Let  $E$  be a closed subset of  $\mathbb{T}$  of Lebesgue-measure 0, let  $f$  be a continuous function on  $E$ , and let  $T$  be a subset of  $\mathbb{C}$  homeomorphic to  $\overline{\mathbb{D}}$  such that  $f(\overline{\mathbb{D}}) \subset T$ . Then there exists an  $F \in \mathcal{A}$ , such that  $F = f$  on  $E$  and  $F(\overline{\mathbb{D}}) \subset T$ .*

This will be proved as Rudin did it in his original paper [Rudin, 1956]. We will break the proof into several lemmas. The first few lemmas are dedicated to showing the result holds for continuous simple functions, and the last lemma bridges the gap.

**Lemma 3.2.3.** Let  $H$  be a closed set of Lebesgue-measure zero. Then there exists a function  $h : \mathbb{T} \rightarrow [1, \infty]$  such that

1.  $h$  is in  $L^1(\mathbb{T}, \sigma)$
2.  $h|_{\mathbb{T} \setminus H}$  is in  $C^\infty$ .
3.  $h(z) = \infty$  if and only if  $z$  is in  $H$ .

4.  $\lim_{w \rightarrow z} h(w) = \infty$  for all  $z$  in  $H$ .

Recall from set theory that if  $(X, d)$  is a metric space,  $A$  is a subset of  $X$  and  $x$  is a point of  $X$  then the distance between  $x$  and  $A$  is

$$d(x, A) = \inf_{a \in A} d(x, a).$$

Furthermore, if  $A$  is closed then the infimum is obtained at some of  $A$ , namely, there exists a point  $y \in A$  such  $d(x, y) = d(x, A)$ . Let  $X = [0, 1]$  and  $H$  be some closed set of Lebesgue-measure zero. We will, for reasons that will be made clear later, assume that  $0, 1 \in H$ . We can now define function  $V_H : [0, 1] \rightarrow [0, 1]$  and  $H_H : [0, 1] \rightarrow [0, 1]$  such that

$$d(x, H \cap [0, x]) = d(x, V_H(x)) \quad \text{and} \quad d(x, H \cap [x, 1]) = d(x, H_H(x)).$$

Intuitively,  $H_H(x)$  is the point in  $H$  that's to the right of  $x$  and is closest to  $x$  and  $V_H(x)$  is the point in  $H$  that's to the left of  $x$  and is closest to  $x$ . So all points  $x$  in  $[0, 1] \setminus H$  are on the open interval  $]V_H(x), H_H(x)[$ . We will define function  $f : [0, 1] \rightarrow [0, \infty]$  by

$$f_H(x) = 2 \log \left( \frac{H_H(x) - V_H(x)}{2} \right) - \log((x - V_H(x))(H_H(x) - x))$$

and show that this is the desired function.

Figure 3.2: An example of  $f_H$  where  $H$  includes nine points. The points of  $H$  are represented by circles.

### 3. Rudin-Carleson theorem

Let's first define a family of functions indexed with  $a, b \in \mathbb{R}$  by

$$f_{a,b} : [a, b] \rightarrow [0, \infty], x \mapsto 2 \log \left( \frac{b-a}{2} \right) - \log((x-a)(b-x))$$

and show they satisfy the following properties:

1.  $f_{a,b}(a + (b-a)2^{-n}) \leq n$ ,
2.  $f_{a,b}(x) = f_{a,b}(b + a - x)$ .

Figure 3.3: The graph of  $f_{0,1}$  and  $g_{0,1}$ .

The first point gives us a handy estimate and the second tells us  $f_{a,b}$  is symmetric around  $(a+b)/2$ . Note that for the first point it suffices to consider when  $a = 0$ , since  $a$  denotes a simple translation. We then have that

$$\begin{aligned} f_{0,b}(b2^{-n}) &= 2 \log b - 2 \log 2 - \log(b2^{-n}(b - b2^{-n})) \\ &= 2 \log b - 2 \log 2 - \log b + n \log 2 - \log b - \log(1 - 2^{-n}) \\ &= n - (2 + \log(1 - 2^{-n})) \\ &\leq n. \end{aligned}$$

To show the second property we consider the case where  $a = -b$ , that is we translate so that the midpoint between them is 0. Then

$$\begin{aligned} f_{-b,b}(-x) &= 2 - \log((-x+b)(b+x)) \\ &= 2 - \log((b-x)(x-(-b))) \\ &= f_{-b,b}(x). \end{aligned}$$

These two points together tell us that we can bound  $f_{a,b}$  above by

$$g_{a,b}(x) = \begin{cases} n, & \text{if } 2^{-n} \leq \frac{x-a}{b} < 2^{-n+1} \\ g(a+b-x), & \text{if } \frac{x-a}{b} > \frac{1}{2} \end{cases},$$

namely a function taking integer values. It is more convenient to look at  $g_{a,b}$  instead of  $f_{a,b}$  because the former can trivially be shown to be the limit of a monotone sequence of simple functions. Let's look at the case where  $a = 0$  and  $b = 1$ . Let  $g = g_{0,1}$  and

$$g_n(x) = \begin{cases} g(x), & \text{if } g(x) \leq n \\ 0, & \text{else.} \end{cases}$$

We can now integrate  $g$  by

$$\begin{aligned} \int g \, d\sigma &= \int \lim_{n \rightarrow \infty} g_n \, d\sigma \\ &= \lim_{n \rightarrow \infty} \int g_n \, d\sigma \\ &= \lim_{n \rightarrow \infty} \sum_{k=1}^n k 2^{-k} \\ &= \sum_{k \in \mathbb{N}} k 2^{-k} \\ &< \infty \end{aligned}$$

where the second equality is by monotone convergence and the last is by some test. This rationale also holds for general  $a$  and  $b$ , since  $a$  does not effect the value of the integral and  $b$  scales it.

Let's now go back to  $f_H$ . Note that we can locally look at  $f$  as a function in  $\{f_{a,b}\}_{a,b \in [0,1]}$ , that is,  $f(x) = f_{V_H(x), H_H(x)}(x)$ . We can define a function

$$g_H(x) = g_{V_H(x), H_H(x)}(x)$$

and a sequence of functions

$$g_n(x) = \begin{cases} g_H(x), & \text{if } g_H(x) \leq n \\ 0, & \text{else.} \end{cases}$$

We have that  $(g_n)_{n \in \mathbb{N}}$  is monotone with limit  $g$ , similar to before, and  $f \leq g$ . Note that, independent of  $H$ , we have

$$\sigma(f_H^{-1}(k)) = 2^{-k}$$

### 3. Rudin-Carleson theorem

so

$$\begin{aligned}
 \int f_H \, d\sigma &\leq \int g_H \, d\sigma \\
 &= \int \lim_{n \rightarrow \infty} g_n \, d\sigma \\
 &= \lim_{n \rightarrow \infty} \int g_n \, d\sigma \\
 &= \lim_{n \rightarrow \infty} \sum_{k=1}^n k 2^{-k} \\
 &= \sum_{k \in \mathbb{N}} k 2^{-k} \\
 &< \infty
 \end{aligned}$$

by the same reasoning as before.

Figure 3.4: An example of  $f_H$  where  $H$  includes several points. The points of  $H$  are represented by circles.

Note that we left some fundamentals unmentioned. Specifically the fact that  $f_H$  and  $g_H$  are measurable. To show that  $g$  is measurable it suffices to show that  $(g_n)_{n \in \mathbb{N}}$  are measurable. We, therefore, can show that the preimage under  $g_n$  of each point is measurable, since  $g_n$  is simple, for each  $n$ . But the preimage is a (possibly uncountable) union of half-open intervals so it is the union of a closed set and an

open set. So  $g$  is measurable. To show that  $f$  is measurable it suffices to show that  $P_\lambda = \{x \in [0, 1]; f(x) < \lambda\}$  is measurable for all  $\lambda$  in  $[0, \infty]$  [Tao, 2014, lemma 1.3.9]. This trivially holds, since  $P_\lambda$  is open.

*Proof of 3.2.3.* We may assume that  $H$  is not empty, since the statement holds vacuously if that were the case. Let  $f$  be as described above,  $g : \mathbb{T} \rightarrow [0, 1]$  such that  $g|_{[0, 1]}$  is a diffeomorphism,  $g(0) = g(1)$ , and  $g^{-1}(0)$  is in  $H$ , and let  $h = 2 + f \circ g$ .  $\square$

**Lemma 3.2.4.** If  $f$  is a simple continuous function on  $E$  such that  $\operatorname{Re} f \geq 0$ , then there exists an  $F \in \mathcal{A}$  such that  $F = f$  on  $E$  and  $\operatorname{Re} F \geq 0$  on  $\overline{\mathbb{D}}$ .

*Proof.* It suffices to show that this holds if  $f$  takes only two values on  $E$ , since simple functions are finite linear combinations of characteristic functions. Let's assume these values are 0 and  $\alpha \neq 0$ , with  $\operatorname{Re} \alpha \geq 0$ ,  $E_0 = f^{-1}(0)$ , and  $E_1 = f^{-1}(\alpha)$ . Our assumption that  $f$  only takes two values then implies that  $E_0 \cup E_1 = E$ .

Let  $u_H(z)$  be the Poisson integral of the function from 3.2.3. This function is continuous on  $\mathbb{T} \setminus H$ ,  $u_H|_H = \infty$ , and  $\lim_{z \rightarrow w} u_H(z) = \infty$  for  $w \in H$  [Rudin, 1987, page 234]. Let's set  $v_H$  as the conjugate harmonic of  $u_H$  and define

$$g_H(z) = \begin{cases} u_H(z) + iv_H(z), & z \in \mathbb{D} \setminus H \\ \infty, & \text{otherwise} \end{cases}.$$

By our construction of  $u_H$  we see the  $\operatorname{Re} g_H > 1$ , so it has a well defined square root. Let's call it  $h_H$  and define

$$q = \frac{h_{E_1}}{h_{E_0} + h_{E_1}}.$$

Note that  $|\arg h_H(z)| \leq \pi/4$  since if a  $w \in \mathbb{C}$  had an argument outside of this range then its square would have an argument outside of the range  $[-\pi/2, \pi/2]$  meaning  $\operatorname{Re} w^2 < 0$ . Also,  $q(z) = 0$  if and only if  $h_{E_0} = \infty$ , so  $q$  is zero only on  $E_0$ , and  $q(z) = 1$  if and only if  $h_{E_1} = \infty$ , so  $q$  is one only on  $E_1$ . We now want to show that  $0 \leq \operatorname{Re} q \leq 1$ . We will let  $z, w \in \mathbb{C}$ , with  $|\arg z|, |\arg w| < \pi/4$  and  $\operatorname{Re} z, \operatorname{Re} w > 1$ , and show that  $0 < \operatorname{Re} z/(w + z) < 1$ .

Note first that

$$\frac{z}{w + z} = \frac{1}{w/z + 1}$$

so

$$\arg \frac{z}{w + z} = -\arg \left( \frac{w}{z} + 1 \right)$$

and

$$|\arg w/z| = |\arg w - \arg z| \leq |\arg w| + |\arg z| < \pi/4 + \pi/4 = \pi/2.$$

### 3. Rudin-Carleson theorem

So  $w/z$  is in the right halfplane and, therefore  $w/z + 1$  is as well. So  $0 < \operatorname{Re} z/(w+z)$ . Note that  $0 < \operatorname{Re} z/(w+z) \implies 0 > \operatorname{Re} -w/(w+z)$  due to  $z$  and  $w$  being constrained in the same manner. So

$$\begin{aligned} 0 &> \operatorname{Re} \frac{-w}{w+z} \\ &= \operatorname{Re} \frac{z - (z+w)}{w+z} \\ &= \operatorname{Re} \left( \frac{z}{w+z} - 1 \right) \\ &= \operatorname{Re} \frac{z}{w+z} - 1 \\ \implies 1 &> \operatorname{Re} \frac{z}{z+w}. \end{aligned}$$

So we have shown that

$$0 < \operatorname{Re} \frac{z}{z+w} < 1.$$

We have now constructed a function  $q$  that maps  $\overline{\mathbb{D}}$  to the ribbon  $\{z; 0 \leq \operatorname{Re} z \leq 1\}$ . We then let  $\Phi$  be the conformal mapping from the ribbon  $\{z; 0 \leq \operatorname{Re} z \leq 1\}$  to  $\{z; 0 \leq \operatorname{Re} z \leq \operatorname{Re} \alpha\}$ . We will also choose  $\Phi$  such that  $\Phi(0) = 0$  and  $\Phi(1) = \alpha$ . We can then let  $F = \Phi \circ q$  and conclude the proof.

□

**Lemma 3.2.5.** If  $f$  is a simple continuous function on  $E$  that maps  $E$  into  $T \subset \mathbb{C}$  homeomorphic to  $\overline{\mathbb{D}}$ , then there exists a  $F \in \mathcal{A}$ , such that  $F = f$  on  $E$  and  $F$  maps  $\overline{\mathbb{D}}$  into  $T$ .

*Proof.* Let  $z_0 \in T \setminus f(E)$  and  $\Phi$  be a conformal mapping from the right halfplane to the interior of  $T$  such that  $\Phi(\infty) = z_0$ . There exists a  $g \in \mathcal{A}$  that extends  $\Phi^{-1} \circ f$ , according to Lemma 3.2.4. The desired function is then obtained with  $F = \Phi \circ g$ . □

**Lemma 3.2.6.** If  $f$  is a continue function on  $E$  which maps  $E$  into  $S$  then there exists a sequence  $(f_n)_{n \in \mathbb{N}}$  of simple continuous function on  $E$  such that

$$f(x) = \sum_{n \in \mathbb{N}} f_n(z) \text{ and } f_n(E) \subset 2^{-n}S.$$

*Proof.* We will set  $f_0 = 0$  and construct  $f_n$  iteratively. Assuming  $f_0, f_1, \dots, f_{n-1}$  have been constructed such that

$$\lambda_{n-1}(E) \subset 2^{1-n}S$$

with  $\lambda_{n-1} = f - \sum_{k=0}^{n-1} f_k$ . According to 3.2.1 we have can write  $E$  as the union of disjoint closed sets  $E_1, E_2, \dots, E_p$  such that the oscillation of  $\lambda_{n-1}$  is less than  $2^{-n}$  on each  $E_k$ . So we can define  $Q_k \subset 2^{1-n}S$  for  $k = 1, 2, \dots, p$  such that  $Q_k = 2^{-n}S + a_k$  for some  $a_k \in S$ . We can choose  $c_k \in Q_k \cap 2^{-n}S$  since  $Q_k$  has side length  $2^{-n}$  and is a subset of  $2^{-n+1}$  and both are closed. We can now define

$$f_n(z) = c_k, \quad z \in E_k, \quad k = 1, 2, \dots, p.$$

If we then look at  $\lambda_n = f - \sum_{k=0}^n f_k = \lambda_{n-1} - f_n$  we see that  $\lambda_n(E) \subset 2^{-n}S$  due to the way we decomposed  $E$  into  $E_1, E_2, \dots, E_p$  using the oscillations of  $\lambda_{n-1}$ . This means we can continue the process.  $\square$

*Proof of 3.2.2.* Let's first show the result for  $T = S$ .

Let  $f_n$  be the functions from Lemma 3.2.6. According to Lemma 3.2.5 we have functions  $g_n \in \mathcal{A}$  which extend  $f_n$  and map  $\overline{\mathbb{D}}$  into  $2^{-n}S$ . We then define

$$F = \sum_{n \in \mathbb{N}} g_n$$

on  $\overline{\mathbb{D}}$ . To show that  $F$  is in  $\mathcal{A}$  it suffices to show that series converges uniformly. Let  $M_n = 2^{-n+1}$  and note that  $|g_n(z)| \leq \sqrt{2} \cdot 2^{-n} < 2^{-n+1} = M_n$  and

$$\sum_{n \in \mathbb{N}} M_n = \sqrt{2} \sum_{n \in \mathbb{N}} 2^{-n} = \sqrt{2} < \infty$$

so the Weierstrass M-test tells us that  $F$  converges uniformly. We also have that

$$\operatorname{Re} F = \sum_{n \in \mathbb{N}} \operatorname{Re} g_n \leq \sum_{n \in \mathbb{N}} 2^{-n} = 1.$$

It can be shown in the same manner that  $\operatorname{Im} F \leq 1$ , so  $F$  maps into  $S$ . Lastly, for  $z \in E$  we have that

$$F(z) = \sum_{n \in \mathbb{N}} g_n(z) = \sum_{n \in \mathbb{N}} f_n(z) = f(z)$$

so  $F$  is an extension of  $f$ .

To prove the result for a general  $T$  we first let  $\Phi : T \rightarrow S$  be the map provided to us by 2.2.7. We will also let  $g = f \circ \Phi$ . Note that it maps  $E$  into  $S$ , so we can use what we showed above to find  $G \in \mathcal{A}$  that extends  $g$  and maps into  $S$ . We finally set  $F = G \circ \Phi^{-1}$ . On  $E$  we have that

$$F = G \circ \Phi^{-1} = g \circ \Phi^{-1} = f \circ \Phi \circ \Phi^{-1} = f,$$

so  $F$  extends  $f$ . It is also a composition of functions in  $\mathcal{A}$  so it is also in  $\mathcal{A}$ .  $\square$

### 3.3. A generalization of the Rudin-Carleson theorem

This borrows from [Bishop, 1962].

**Theorem 3.3.1** (General Rudin-Carleson theorem). *Let  $X$  be a compact Hausdorff space,  $V = (C(X), \|\cdot\|_\infty)$ ,  $B$  be a closed subspace of  $C(X)$ ,  $B^\perp$  be the annihilating measures of  $B$ ,  $S$  be a closed subset of  $X$  that is  $\mu$ -null for all  $\mu \in B^\perp$ ,  $f$  be a continuous function on  $S$ , and  $\Xi > 0$  be a continuous function on  $X$  such that  $|f| < \Xi$  on  $S$ . Then there exists a  $F \in B$  such that  $F = f$  on  $S$  and  $|F| < \Xi$  on  $X$ .*

Let's start with the following lemma:

**Lemma 3.3.2.** Assume  $|f| < r < 1$  on  $S$ . Then there exists a  $F \in B$  such that  $F = f$  on  $S$  and  $\|F\| < 1$ .

*Proof.* Let  $U_r$  be the subset of  $B$  defined by  $U_r = \{g; \|g\| < r\}$  and  $\phi$  be the mapping from  $B$  to  $C(S)$  that sends a member of  $B$  to its restriction on  $S$ . It suffices to show that  $f \in \phi(U_r)$ . Let's first show that  $f \in \overline{\phi(U_r)} =: V_r$ , by assuming otherwise, and showing it leads to a contradiction. Note that if  $f, g \in U_r$  and  $t \in [0, 1]$  then

$$\|tf + (1-t)g\| \leq t\|f\| + (1-t)\|g\| \leq tr + (1-t)r = r$$

so  $tf + (1-t)g$  is also in  $U_r$ , showing it is convex. Its closure,  $V_r$ , is then convex as well.

By Hahn-Banach we can define a bounded linear functional  $\alpha$ , such that  $\alpha(f) > 1$  and  $|\alpha| < 1$ , on  $V_r$ . We can then define a measure  $\mu_1$  by the Riesz representation theorem that satisfies

$$\alpha(g) = \int g \, d\mu_1$$

for all  $g \in C(S)$ . We will refer to the associated functional on  $B$  by  $\beta(g) = \alpha(\phi(g))$ . Since  $\phi(g) \in V_r$  for all  $g \in U_r$  we have that

$$\beta(g) = \alpha(\phi(g)) < 1,$$

for all  $g \in U_r$ , due to the construction of  $\alpha$ . From this we get

$$\begin{aligned} \|\beta\| &= \sup\{|\beta(g)|; \|g\| < 1\} \\ &= \sup\{(1/r)|\beta(g)|; \|g\| < r\} \\ &\leq 1/r. \end{aligned}$$

### 3.3. A generalization of the Rudin-Carleson theorem

Let's denote the Riesz representation of  $\beta$  by  $\mu_2$ , set  $\mu = \mu_1 - \mu_2$ , and note that  $\mu \in B^\perp$ . But

$$0 = \left| \int_S f \, d\mu \right| \geq \int_S f \, d\mu_1 - r\|\mu_2\| \geq \int_S f \, d\mu_1 - r\frac{1}{r} > 1 - r\frac{1}{r} = 0.$$

This is the contradiction that gives that  $f \in V_r$ . We can now take a  $F_1$  in  $U_r$ , and therefore also in  $B$  such that  $|f - F_1| < \lambda/2$  on  $S$ , with  $\lambda := 1 - r$ . Remember that  $F_1 \in U_r$  implies that  $\|F_1\| < r$ . Now let  $f_1 = f - F_1$  and use the same method as above to obtain an  $F_2$  such that  $\|F_2\| < \lambda/2$  and  $|f - F_2| < \lambda/4$  on  $S$ . Iterating this process yields a sequence  $(F_n)_{n \in \mathbb{N}}$  from  $B$  such that  $\|F_n\| < 2^{1-n}\lambda$  for  $n > 1$  and

$$\left| f - \sum_{k=1}^n F_k \right| < 2^{-n}\lambda$$

on  $S$  for  $n > 1$ . We finally let

$$F = \sum_{k=1}^{\infty} F_k.$$

Now  $F \in B$ ,

$$\|F\| \leq \|F_1\| + \|F - F_1\| \leq r + \sum_{k=2}^{\infty} 2^{1-k}\lambda = r + \lambda = 1,$$

and  $F = f$  on  $S$ . □

*Proof of 3.3.1.* Let  $B_0$  be the closed subspace of  $C(X)$  consisting of function  $g$  such that  $\Xi \cdot g \in B$ . We have that  $B_0^\perp = B^\perp$ , since  $\Xi > 0$ . So we can use Lemma 3.3.2 for  $B_0$  instead of  $B$  and  $f/\Xi$  instead of  $f$ . This gives us a  $F_0 \in B_0$  such that  $\Xi \cdot F_0 = f$  on  $S$  and  $\|F_0\| < 1$ . We set  $F = \Xi \cdot F_0$  which is in  $B$  by the construction of  $B_0$ . Also note that  $|F| < \Xi$  on  $X$  and

$$F = \Xi \cdot F_0 = \Xi \cdot f/\Xi = f$$

on  $S$ . □

*Alternative proof of 3.2.2.* Let  $X = \mathbb{T}$ ,  $B = \mathcal{A}|_{\mathbb{T}}$ , and  $S$  be a closed set of Lebesgue-measure zero. Then, according to 3.1.14,  $S$  is also a  $B^\perp$ -null. So all requirements of 3.3.1 are met. □

# A. A further application of the general Rudin-Carleson theorem

**Definition A.0.1.** Let  $K$  be a closed subset of  $S = \{z \in \mathbb{C}^n; |z| = 1\}$ . We then say  $K$  is a

1. *zero set* if there exists a function in  $f \in \mathcal{A}^n$  such that  $K = f^{-1}(0)$ .
2. *peak set* if there exists a function in  $f \in \mathcal{A}^n$  such that  $K = f^{-1}(1)$  and  $|f(z)| < 1$  for  $z \in \overline{\mathbb{B}}^n \setminus K$ .
3. *interpolation set* if every continuous function on  $K$  extends via  $\mathcal{A}^n$ .
4. *peak-interpolation set* if every non-zero continuous function  $f$  on  $K$  extends to  $F \in \mathcal{A}^n$  such that  $|f(z)| < \|F\|$  for  $z \in \overline{\mathbb{B}}^n \setminus K$ .
5. *null set* if  $K$  has measure zero with regards to all annihilating measures of  $\mathcal{A}^n$ .
6. *totally null* if  $K$  has measure zero with regards to all measure  $\mu$  such that

$$f(0) = \int_{\mathbb{B}} f \, d\mu$$

for all  $f \in \mathcal{A}^n$ .

**Theorem A.0.2.** *The six classes of sets described in A.0.1 are equivalent.*

The first few sections of chapter 10 in [Rudin, 1980] are dedicated to prove this large theorem. One implication, namely that all null sets are peak-interpolation sets, follows directly from 3.3.1.
